Crk, the prototypical member of a class of Src homology–2 (SH2) and Src homology–3 (SH3) domain containing proteins that controls the coordinated assembly of signaling complexes, is regulated by phosphorylation of Y221 in the linker region, which forms an intramolecular SH2-pY221 auto-clamp to interrupt SH2-N-terminal SH3 domain (SH3N) signaling. Here, we show using LC-MS/MS and by generating phospho-specific antibodies that, iteratively with Y221, the Crk C-terminal SH3 domain (SH3C) is routinely phosphorylated on Y239 and/or Y251 by several extracellular stimuli known to engage Crk. Although phosphorylation at Y221 auto-inhibits the Crk SH2, phosphorylation of the SH3C generates an unconventional phosphoSH3C-SH3N unit in which the SH3N is fully functional to bind polyproline type II ligands and the phosphoSH3C binds *de novo* to other SH2 domains. Using high-throughput SH2 domain profiling, artificial neural network and position-specific scoring matrix-based bioinformatics approaches, and unbiased mass spectometry, we found that the phosphoSH3C binds several SH2 domain containing proteins, including specific non-receptor tyrosine kinases–Abl via pY251 and C-terminal Src kinase via pY239. Functionally, we show that the phosphoSH3C modulates the Abl-mediated phenotypes of cell spreading and motility. Together, these studies describe a versatile mechanism wherein phosphorylation of Crk at Y221 is not an off switch but redirects signaling from the SH2–SH3N axis to a phosphoSH3C-SH3N axis, with the SH3N as a common denominator.

INTRODUCTION

The Src homology-2 (SH2) and Src homology-3 (SH3) domain containing Crk family of adapter proteins assemble proteinprotein complexes in a spatially and temporally regulated manner during cell adhesion, migration and efferocytosis.^{1–6} Crk signaling is mediated by the coordinated recruitment of specific tyrosine phosphorylated proteins, such as paxillin and p130cas, via the SH2 domain in the context of pY.X.X.P whereas the N-terminal SH3 domain (SH3N) domain recruits specific guanine nucleotide exchange factors DOCK180 or C3G, by binding to conventional polyproline type II (PPII) motifs in the context of P.X.X.P.X. (K/R).⁷⁻¹⁰ DOCK180 and C3G, in turn, activates the Rac1 and Rap1 GTPases, respectively,^{11,12} which regulate cell migration or cell spreading. Signal transduction by CrkII and CrkL is negatively regulated by phosphorylation at Y221 (on CrkII) and Y207 (on CrkL)^{13–15} to bring about an intramolecular association of the pY221 motif with the Crk SH2 domain thereby causing disassembly of Crk from proteins bound in trans to the SH2 domain.¹⁶

The C-terminal SH3 domain (SH3C) of Crk is an atypical SH3 domain which, unlike the SH3N, does not bind conventional PPII motifs.^{17,18} In contrast to the surface of the SH3N that has a hydrophobic ligand binding pocket lined by W169, Y186 and F141, the surface of the SH3C is lined by polar residues—Q244, H290 and Q274. *Cis-trans* isomerization about the G237–P238 peptide bond in the chicken CrkII SH3N–SH3C unit has been shown to control accessibility of ligands to the SH3N where in the *cis* configuration,

the SH3C engages the PPII binding pocket on the SH3N.^{19,20} In human CrkII, the SH3N is negatively regulated by the SH3C and the inter-SH3 core region—residues 224–37,²¹ which was shown to assemble CrkII into a structural state that resulted in reduced affinity for a PPII peptide derived from Sos1. These observations offer a molecular mechanism to explain why mutations or truncations in the SH3C activate the adapter protein function of Crk. However, independent of its role in regulation of the SH3N, the physiological role of the SH3C in the context of Crk signaling is poorly understood.

Here, we found that both Y251 in the RT loop and Y239 at the SH3C boundary are iteratively and routinely phosphorylated with Y221, but at different stoichiometry with different extracellular stimuli. Although phosphorylation at Y221 auto-inhibits the SH2 domain, it simultaneously generates a non-canonical phosphoSH3C-SH3N unit in Crk, with the SH3N as a common denominator. Our results define an affirmative role for the SH3C in signal transduction, and posit that phosphorylation at Y221 is not exclusively an off switch but redirects signaling by differential coupling of modular domains in Crk.

Historically, studies on Crk have impacted signal transduction by providing a paradigm for physical coupling by modular SH2 and SH3 domains. Here, we describe a novel paradigm whereby iterative tyrosine phosphorylation controls differential utilization of modular domains in Crk. Phosphorylation at Y221 functionally interrupts the SH2–SH3N axis whereas phosphorylation at Y239/Y251 iteratively with Y221 generates an unconventional

phosphoSH3C-SH3N signaling unit. Our study presents a conceptual advance in the field by highlighting a novel role of tyrosine phosphorylation in regulating modular domain utilization in Crk. Future studies aimed to identify the repertoire of tyrosine kinases that control Y239 and Y251 phosphorylation, as well as identification of tumor types that dysregulate these phosphorylation events will greatly impact research on Crk biology.

RESULTS

Identification of tyrosine phosphorylation sites on the Crk SH3C domain by LC-MS/MS

The Crk SH3C is an atypical SH3 domain that has distinct surface chemistry compared with conventional SH3 domains and does not bind conventional PPII motifs. Henceforth, unless otherwise specified, CrkII will be referred to as Crk, and 'p' denotes phosphotyrosine. By LC-MS/MS based phosphopeptide mapping of Crk following incubation with recombinant Abl kinase *in vitro*, three phosphorylation sites in the human Crk C-terminus were identified (i) Y251 in the extended RT loop structure, (ii) Y239 at the boundary of the SH3C domain and (iii) Y221 previously identified as a motif that binds intramolecularly to the Crk SH2 domain to achieve auto-inhibition (Figures 1a, b and d).

Specific receptor tyrosine kinases induce distinct pY221/pY239/ pY251 phosphorylation patterns on Crk

By generating affinity-purified phospho-specific antibodies toward the pY239 and pY251 phosphopeptide motifs, and using an available commercial anti-pY221 antibody, all three sites were found to be phosphorylated iteratively *in vitro* (Figure 1c) and in cells (Figure 2a) when Crk was co-expressed with Abl-1b (lane 6), consistent with the results of the LC-MS/MS analysis. Expression of individual point mutants of Crk shows the exquisite specificity of these antibodies (lanes 7–9), as no cross-reactivity was noted (Figure 2a).

To examine whether tyrosine kinases other than Abl could induce pY239 and pY251, we analyzed endogenous pathways that have been implicated in Crk signaling. Towards this goal, we used (i) epidermal growth factor receptor (EGFR)-expressing MDA-MB-468 human breast cancer cells (ii) PDGF β R-expressing mouse NIH 3T3 cells (iii) hepatocyte growth factor receptor (HGFR or c-Met) expressing MDA-MB-231 human breast cancer cells and (iv) NIH 3T3 cells plated on fibronectin, which engages integrinmediated signaling via Crk.^{2,22} EGFR, PDGF β R and HGFR have all been implicated in Crk signaling.^{23–27} We also examined Crk tyrosine phosphorylation downstream of the TAM family of tyrosine kinases, as Crk has a pre-eminent role in TAM-mediated efferocytosis of apoptotic cells.^{6,28}

Figure 2b shows experiments which involved no ectopic overexpression of growth factor receptor or Crk (see Supplementary Figure S1B and Supplementary Table ST5 for quantification). Interestingly, EGF and fibronectin preferentially induced pY251 and pY221 (panel 1) whereas PDGF-BB preferentially induced pY239 and pY221 (panel 3) and hepatocyte growth factor preferentially induced pY221 (panel 2), but not pY239 or pY251. Finally, we examined Crk phosphorylation downstream of constitutively active flag-tagged Fc-Tyro3 and Fc-Mer fusion

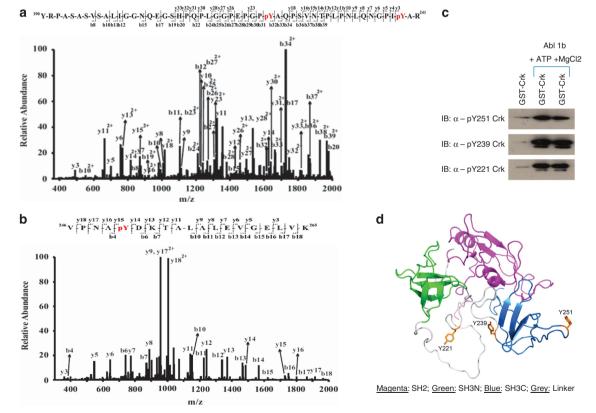

Figure 1. Identification of phosphorylation sites pY221, pY239 and pY251 on Crk by LC-MS/MS. (a) MS/MS spectrum of a quadruply-charged ion (m/z 1371.16) corresponding to a doubly phosphorylated peptide ¹⁹⁰YRPASASVSALIGGNQEGSHPQPLGGPEPGPpYAQPSVNTPLPNLQNGPIpYAR²⁴¹ is shown. The phosphorylation sites are Y221 and Y239. (b) MS/MS spectrum of a doubly charged ion (m/z 1055.53) corresponding to the peptide sequence ²⁴⁷VPNApYDKTALALEVGELVK²⁶⁴ with a phosphorylation modification at Y251 is shown. The observed **y**- and **b**-ion series confirmed the peptide sequence and modification. (c) GST-Crk was *in vitro* phosphorylated by immunoprecipitated Abl-1b in a kinase reaction and samples were analyzed by western blotting with anti-pY221 Crk (bottom), anti-pY239 Crk (middle) and anti-pY251 Crk (top) antibodies. (d) Locations of Y239 and Y251 on the SH3C and Y221 on the inter-SH3 linker are depicted on the solution structure of Crk (PDB ID: 2EYZ).

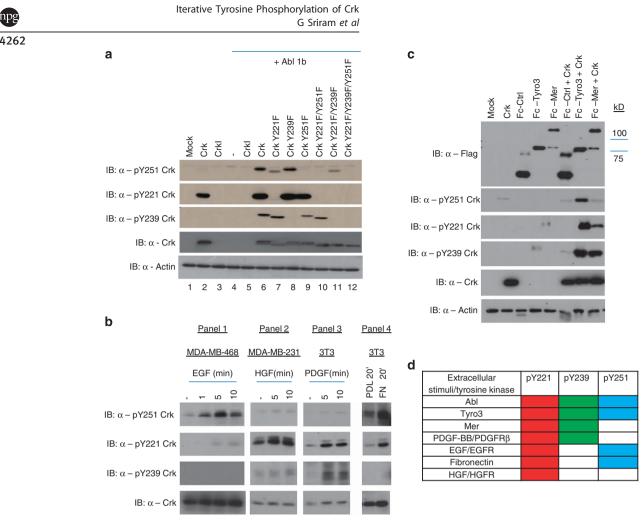

Figure 2. RTKs show distinct preferences for phosphorylation of Crk at Y221/Y239/Y251. (**a** and **c**) 293 T cells were transfected with the plasmids indicated and lysates were analyzed by western blotting with the antibodies shown on the left. (**b**) MDA-MB-468 cells were stimulated with EGF (panel 1), MDA-MB-231 cells with HGF (panel 2) and NIH 3T3 cells with PDGF-BB (panel 3) for the times indicated or plated on Poly-D-Lysine or Fibronectin-coated dishes for 20 min (panel 4). Samples were analyzed by western blotting with the antibodies indicated on the left. (**d**) Summary of Crk phosphorylation patterns observed. Red, green and blue indicate positive for pY221, pY239 and pY251 respectively.

proteins. Fc-Mer preferentially induced pY221 and pY239 (Figure 2c, Supplementary Figure S1A), whereas Fc-Tyro3 induced pY221, pY239 and pY251. Taken together, these results suggest that EGFR, PDGFR, HGFR, Tyro3 and Mer, display distinct preferences for phosphorylation of Crk at Y221/Y239/Y251 (Figure 2d). Notably, in all cases examined to date, Y239 and Y251 on the SH3C are phosphorylated iteratively with Y221.

The Crk SH3N domain is accessible to ligands in SH2-autoinhibited (pY221-phosphorylated) Crk

By using high-resolution nuclear magnetic resonance (NMR) to study the effect of tyrosine phosphorylation on structural rearrangements in Crk, we observed that the chemical shift differences ($\Delta\delta$) between unphosphorylated (Crk) versus phosphorylated Crk (pCrk) revealed major shifts in the SH2 domain and the region around Y221 consistent with phosphorylation at Y221 and intramolecular pY221-Crk SH2 association (Figure 3a, stoichiometry of phosphorylation at Y221 was >95% by NMR). Notably, no drastic changes in the SH3N domain were observed, as exemplified by residues lining the SH3N-PPII binding pocket— F141, W169 and Y186 (Supplementary Figure S2), suggesting that the Crk SH3N did not undergo a major change in accessibility upon phosphorylation at Y221 and intramolecular pY221-SH2 association. By comparing SH3N accessibility using a Crk SH3N-specific C3G PPII peptide with the sequence N-DNSPPPALPPKKRQSAPS-C,²⁰we observed that the SH3N was accessible to its PPII ligand in both Crk and pCrk as shown by shifts in the NMR peaks for F141, W169 and Y186 (Figure 3b). Consistently, binding affinities of Crk and pCrk for the C3G PPII peptide by ITC (Figure 3c) were similar (~2 μ M) demonstrating that the Crk SH3N remains accessible to ligands upon phosphorylation at Y221 and intramolecular pY221-Crk SH2 association.

Furthermore, we tested whether pY221-phosphorylated Crk can interact with a known physiological binding partner (Figure 3d). Binding of Flag-Paxillin, an SH2 binding partner, to pCrk was greatly reduced compared with Crk consistent with near complete stoichiometry of phosphorylation at Y221. Concomitantly, GST-Crk was also phosphorylated at Y239 suggesting that the SH3C was accessible to phosphorylation and could form protein-protein interactions and possibly signaling complexes. In contrast, binding of DOCK180, an SH3N binding partner, to pCrk was not blocked suggesting that the Crk SH3N is accessible to its cognate protein ligands upon phosphorylation at Y221 and intramolecular pY221-Crk SH2 association. These results indicate that while phosphorylation at Y221 auto-inhibits the SH2 domain, it simultaneously generates a non-canonical phosphoSH3C-SH3N unit in Crk. To examine if this unit can sustain phosphorylation in cells, we expressed the Crk SH3N-linker SH3C unit (amino acids 123-304 with the Y221F mutation, referred to as S-S) with Abl in 293 T cells

(Figure 3e). While phosphorylation at Y239 and Y251 was retained (although weaker at Y251 compared with WT), the W169K SH3N mutation Abl binding site mutant drastically reduced phosphorylation by Abl suggesting that the SH3N could functionally engage PPII ligands (Abl in this case). These results suggest that in the non-canonical phosphoSH3C-SH3N unit, both phosphorylation on the SH3C and ligand binding to the SH3N, are maintained.

Distinct SH2 domain interaction landscapes for pY239 and pY251 on the phosphorylated Crk SH3C

Given that both Y251 and Y239 on the Crk SH3C were selectively tyrosine phosphorylated by distinct kinases, we hypothesized that each phosphotyrosine motif might also have the potential to recruit phosphotyrosine-specific recognition modules as part of a post-phosphorylation signaling mechanism. To identify binding targets, we used N-terminally biotinylated 16-mer phosphopeptides containing pY239 or pY251 to screen an SH2 domain library side-by-side (Figure 4a, see Materials and methods for details). We identified two types of SH2 domain interactomes. The first group, represented by the Abl, Arg and Sck/ShcB SH2 domains, were common to both phospho-motifs (Figure 4b top panel, Supplementary Table ST1). The second group displayed differential selectivity to one or the other phospho-motifs (Figure 4b, middle and bottom panels). We then generated a profile of selectivity indices wherein selectivity index was defined as the ratio of the binding intensity of an SH2 domain obtained for pY239 to that obtained for pY251 or vice-versa. The maximum selectivity for either peptide in the first group of overlapping hits was not greater than 2.4 (Figure 4c, top panel). Interestingly, in the second group, the pY239-specific hits displayed much higher selectivity (ranging from ~4 to 26) compared with the pY251specific hits (ranging from ~ 1.8 to 2.7). Notably, the top hit for the pY239 peptide was the SH2 domain of C-terminal Src kinase (Csk), which had the maximum selectivity index (~26) of all SH2 domains tested (Figure 4c, middle and bottom panels).

To independently test the SH2 landscapes using a bioinformatics-based approach, we used published Artificial Neural Networks and Position-Specific Scoring Matrices^{29–31} to generate binding profiles for the pY239 and pY251 motifs (Figure 4d and Supplementary Table ST2). Not only were the binding profiles distinct but also consistent with the experimental data shown above, Csk SH2 was the top hit for pY239, and displayed the highest selectivity index (Figure 4e). In contrast, the Abl/Arg SH2 domains were not among the top 10 predicted hits for either peptide.

Complex formation and biological phenotypes influenced by phosphorylation of the Crk SH3C

To experimentally identify protein-protein assemblages mediated by the phosphorylated Crk SH3C domain in MDA-MB-468 cell lysate, we used recombinant, bacterially expressed tyrosine phosphorylated Crk SH3C (herein referred to as pSH3C, see Figure 4f and Materials and methods). Analysis of pSH3C pull downs revealed a major 50 kDa band, specific for pSH3C versus SH3C, which we identified as Csk by LC-MS/MS and confirmed by western blotting (Figure 4g and Supplementary Table ST3). Further, consistent with the *in vitro* SH2 screen and bioinformatic analyses, the pSH3C-Csk complex was pY239 dependent and not pY251 dependent as the Y239F but not the Y251F mutation abrogated the interaction (Figure 4h). As Csk is a negative regulator of Src-family kinases (SFKs), the pSH3C-Csk interaction could potentially activate a positive feed forward loop to sustain Src activation. Consistently, co-transfection of SFKs and Crk induced pY239 on Crk by Hck, Src, Lyn and Blk, which in turn were activated as evident by western blotting with an anti-pY416 SFK antibody that recognizes activated SFKs (Figure 4i).

Despite the fact that both pY239 and pY251 peptides selected Abl and Arg SH2 domains as binding partners in vitro, analysis of the total pSH3C interactome by LC-MS/MS failed to detect Abl/Arg in complex with the pSH3C in the MDA-MB-468 cells (Supplementary Table ST4) suggesting that unlike the pSH3C-Csk interaction, pSH3C-Abl/Arg is not a stand-alone interaction but might rather function within the Crk-Abl complex (already tethered via the Crk SH3N and Abl proline-rich domain^{13,15}) to affect Abl activation. To test this hypothesis both biochemically and functionally, we examined Abl activation and cell spreading on fibronectin, as this is an Abl-modulated phenotype wherein activated Abl inhibits cell spreading.^{32,33} Furthermore, adhesion to fibronectin induces pY251 (and pY221) on Crk. When Crk (-/-) mouse embryonic fibroblasts stably reconstituted with enhanced yellow fluorescent protein (EYFP), Crk WT or Crk Y251F were plated on fibronectin-coated plates, Crk WT enhanced Abl activation whereas Crk Y251F attenuated Abl activation by ~25% (Figure 5a). Also, Crk Y251F accelerated the spreading kinetics of cells compared with Crk WT consistent with the role of activated Abl in inhibiting cell spreading (Figure 5d, top panel).

We also tested an EGF-inducible system wherein Crk is phosphorylated at pY251 and pY221. MDA-MB-468 cells stably expressing Crk WT displayed enhanced Abl activation which was attenuated by Crk Y251F (Figure 5b). Furthermore, Crk Y251F expressing cells displayed attenuated cell motility towards EGF compared with Crk WT (Figures 5c and d, middle panel and Supplementary Figure S3A). Imatinib-treated Crk WT cells displayed an overlapping migration profile to that of Y251F cells suggesting that Crk pY251 promotes cell motility in an Abl kinasedependent manner (Figure 5d, bottom panel). These results suggest that, although Crk pY251-Abl SH2 may not be a standalone interaction, it influences Abl-modulated biological phenotypes by promoting Abl transactivation within the Crk-Abl complex. Consistent with these results, biochemically, Crk pY251 has been shown to promote transactivation of Abl by Crk.³⁴ Furthermore, co-expression of the Crk SH3N-linker-SH3C with Abl in 293 T cells was sufficient to transactivate Abl and was in turn phosphorylated at Y239 and Y251 (Supplementary Figures S3B and 3E). Taken together, these data suggest that the Crk pSH3C-SH3N unit is a functional signaling axis.

DISCUSSION

Despite a high degree of evolutionary conservation, the role of the atypical Crk SH3C domain has remained elusive. Previous studies

suggest that phosphorylation of Crk at Y221 functions as an off switch as it induces SH2 domain auto-inhibition. In this study, we show that iterative tyrosine phosphorylation of Y221 in the linker

Iterative Tyrosine Phosphorylation of Crk

Figure 5. Phosphorylation of the Crk SH3C at Y251 inhibits cell spreading on fibronectin and promotes cell motility towards EGF. (**a**) Crk (-/-) mouse embryonic fibroblasts (MEFs) stably reconstituted with EYFP, Crk WT or Crk Y251F were plated on fibronectin-coated dishes for 20 min. Lysates were analyzed by western blotting with the antibodies shown. Quantification of pY245 on hyperactive Abl is shown on the right. All samples were run on the same gel and hence are comparable. However, the EYFP and WT lanes were not adjacent to the Y251F lane and hence have been demarcated by straight lines at the edges. (**b**) MDA-MB-468 cells stably expressing EYFP, EYFP-Crk WT, EYFP-Crk W7, EYFP-Crk W7, EYFP-Crk W7, EYFP-Crk Y251F were stimulated with EGF for 5 min and lysates were analyzed by western blotting with the antibodies shown. Quantification of pY245 Abl normalized to total Abl is shown on the right. (**c**) Cells in **b** were analyzed for their motility towards EGF in a transwell Boyden chamber assay. Qu

region and within the SH3C (at Y239 and/or Y251) changes the domain utilization in Crk from a SH2–SH3N axis to a non-canonical phosphoSH3C-SH3N axis (Figure 6). Although the repertoire of tyrosine kinases that phosphorylate SH3C is not fully realized, such differential domain utilization rationalizes a new level of complexity and versatility in terms of the adapter protein function of Crk.

An important consequence of the above findings is that phosphorylation at Y221 will not be an endpoint for signaling by Crk when it occurs concomitantly with Y239 and/or Y251 phosphorylation on the SH3C. In support of this model, we observed by NMR, ITC and pull down experiments that Crk can exist in a conformation in which the SH3N remains accessible to ligands after pY221 phosphorylation, whereby the SH2 is occupied by the intramolecular auto-clamp. Plausibly, this permits Crk to retain adapter protein function in conjunction with binding partners engaged by the pY239/pY251 motifs on the SH3C. However, in contrast to our results, Crk has been shown to also adopt a conformation wherein accessibility to the SH3N is drastically reduced upon phosphorylation at Y221 and intramolecular pY221-SH2 association.²¹ Given the conformational versatility inherent in Crk, we do not exclude the possibility that multiple modes of auto-inhibition may exist. This could be achieved by selective phosphorylation at Y221 alone in the absence of SH3C phosphorylation, alternate SH3N-inhibitory

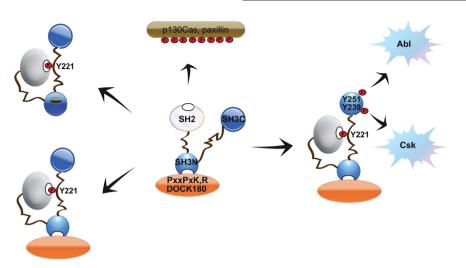

Figure 6. Model depicting a non-canonical signaling scheme for Crk mediated by pY239 and pY251. Our data predict that pY221 would turnoff the SH2–SH3N axis whereas iteratively phosphorylated pY239/pY251 would turn on the pSH3C—SH3N signaling axis predicting a dynamic turnover and/or relocalization of protein complexes. In light of our findings and other independent reports, atleast two modes of auto-inhibition may exist—pY221 alone in the absence of pY239/pY251 (left bottom scenario) on the SH3C or alternate auto-inhibitory domain organization that blocks SH3N accessibility (left top scenario).

domain arrangements in Crk or SH3N post-translational modifications, an example of which would be phosphorylation at Y186 on the Crk SH3N (a conventional SH3 domain) which forms a part of its hydrophobic ligand binding pocket. Phosphorylation of this conserved tyrosine has been shown to reduce the affinity of SH3 domains for ligands in Btk, Abl and p130Cas/BCAR1.^{35–38} However, in our LC-MS/MS analysis, we did not observe phosphorylation of Crk at Y186 (Supplementary Figure S4).

As alluded to above, the possibility of retention of adapter function upon SH3N/PPII engagement in conjunction with complexes formed by pY239/pY251 on the Crk SH3C formed the rationale for identifying SH2 domain containing proteins that bound the pY239/pY251 motifs. The identification of Csk that selectively binds pY239 and not pY251 on the SH3C predicts a specific feed forward loop whereby activation of SFKs could be sustained upon phosphorylation at Y239 on the Crk SH3C. Upon being iteratively phosphorylated with Y221, pY239 on the SH3C would be expected to bind and spatially separate Csk from locations where SFK activity is induced. This suggests a mechanism whereby the kinetics of SFK activation can be fine-tuned to impact relevant biological phenotypes.

Although both the pY239 and pY251 phosphopeptides were selective for the Abl and Arg SH2 domains, the pSH3C-Abl/Arg interaction could not be recapitulated from cells suggesting that whereas the pSH3C-Csk complex can form de novo, the pSH3C-Abl interaction likely has an accessory role within the assembled Crk-Abl complex to impinge on Abl activation by SH2 domain displacement. Consistently, in scenarios where pY251 was induced (iteratively with pY221), the Y251F mutation partially inhibited Abl activation and also influenced the Abl-modulated phenotypes of cell spreading and motility, suggesting that modulation of Abl activity by Crk pY251 is functionally important. Considering the high selectivity observed of pY239 for Csk, we expect that pY251 rather than pY239 would impact Abl activation. Importantly, these findings suggest how signaling downstream of receptor tyrosine kinases (RTKs) can be dissected by Crk to impinge on specific nonreceptor tyrosine kinases—Csk or Abl. This lends new mechanistic insight into how RTKs can specifically induce Csk/Src or Abldependent pathways via the non-canonical (pY239/pY251) SH3C-SH3N module in Crk. As we found distinct patterns of Crk pY221/ pY239/pY251 phosphorylation induced by different factors and kinases, this immediately suggests the possibility to achieve different signaling outcomes via differential Crk phosphorylation. Although we do not exclude the possibility of differentially phosphorylated forms of Crk, we have not observed phosphorylation of Y239 or Y251 in the absence of Y221 phosphorylation under physiological conditions so far. An important future goal will be to identify the full repertoire of tyrosine kinases that impinge on the Crk SH3C and biological contexts in which they segregate to Csk/Src or Abl/Arg pathways.

Finally, in a comparison between Crk and CrkL (Supplementary Figure S5), the residue on CrkL corresponding to Crk-Y239 is phenylalanine suggesting that this pY239-mediated signaling mechanism is specific for Crk. Further, the sequence around Y251 diverges from PNAYDKTALALE on Crk to PCAYDKTALALE on CrkL. This may result in differential binding to PTB domains which recognize residues N-terminal to the phosphorylated tyrosine residue. The Y221/Y207 negative regulatory sites and the Y251 motifs appear to be well conserved across humans, mice, rats, xenopus and chicken whereas the Crk-Y239 motif is conserved across humans, mice, rats and chicken suggesting conservation of function through evolution. Therefore, apart from domain organization differences,³⁹ post-translational modification by phosphorylation at Y239 and/or Y251 likely determines differences in downstream signaling initiated by Crk and CrkL.

MATERIALS AND METHODS

Phospho-specific antibodies

Phospho-specific antibodies to pY239 and pY251 were generated by immunizing rabbits with synthetic 14-mer phosphopeptides corresponding to residues surrounding Y239 and Y251 on Crk, respectively. Antibodies were purified by positive selection on a phosphopeptide-bound column followed by negative selection on a unphosphorylated peptide-bound column.

Cell culture and growth factor stimulation

For stimulation, cells were serum-starved in 0.5% serum for atleast 12 h followed by stimulation with growth factor at 100 ng/ml or held in suspension for 30 min and then plated on dishes coated with either 50 or 100 μ g/ml of poly-D-lysine or fibronectin. Adherent cells were harvested after 20 min.

In vitro phosphorylation

For LC-MS/MS analysis of phosphorylation sites on Crk, bacterially expressed and purified GST- CrkII was incubated with immunoprecipitated

4268

Abl 1b (from 293 T cells) in 50 mM Tris, 150 mM NaCl, 10 mM MgCl₂, 5 mM ATP and 1 mM dithiothreitol at pH 7.5 for 12 h. The reactions were boiled in SDS sample buffer, resolved by SDS–PAGE and stained with SYPRO ruby. The bands corresponding to GST-CrkII were excised and analyzed by LC-MS/MS on an Orbitrap instrument.

Isothermal titration calorimetry and NMR analysis

For NMR, all samples were dialyzed in NMR buffer 50 mM potassium phosphate (pH 6.8), 140 mM NaCl and 1 mM β -mercaptoethanol). NMR experiments were performed on Varian 800- and 600-MHz and Bruker 700- and 600-MHz spectrometers. Abl kinase domain was expressed and purified as described before.^{40,41} Purified and Tev-processed CrkII was phosphorylated by the addition of catalytic amounts of Abl kinase domain in buffer (50 mM KPi (pH 6.8), 150 mM NaCl, 1 mM β -mercaptoethanol) supplemented with 5 mM ATP and 10 mM MgCl₂. The reaction was carried out at room temperature. Stoichiometry of phosphorylation at Y221 was >95% by NMR.

All calorimetric titrations were performed on an iTC200 microcalorimeter (GE, Pittsburgh, PA, USA). Unphosphorylated or phosphorylated CrkII was at 40 μ M in the sample cell and the PPII ligand was at 400 μ M in the injection syringe. Ligand was dissolved in the flow through of the last buffer exchange. Data for the preliminary injection, which are affected by diffusion of the solution from and into the injection syringe during the initial equilibration period, were discarded. The data were fitted with Origin 7.0. (OriginLab corp., Northampton, MA, USA).

GST—pull down experiments

For generation of tyrosine phosphorylated Crk SH3C, the *Escherichia coli* TKB1 strain was used (Stratagene). The Crk SH3C (230–304) was cloned into pET42a under a LacZ promoter and then transformed into the parental *E.coli* BL-21 strain or the TKB1 strain which harbors a plasmid encoding the EphB4 tyrosine kinase domain under a TrpE promoter. IPTG was used to induce synthesis of the GST-SH3C in both BL-21 and TKB1 strains. Addition of Indoleacrylic Acid (IAA) to TKB1 induced synthesis of the EphB4 kinase that phosphorylated GST-SH3C at both Y239 and Y251 to yield pSH3C (Figure 4f). GST-fusion proteins (bait) were then bound to a glutathione-agarose column, washed and incubated with lysates of unstimulated MDA-MB-468 cells. After further washing, bound proteins were eluted with glutathione.

For analysis of SH3N accessibility in full length CrkII, 1 μ m of purified GST-CrkII was phosphorylated by incubating with 10 μ m purified Abl kinase domain in 50 mm Tris, 150 mm NaCl, 10 mm MgCl₂, 5 mm ATP and 1 mm dithiothreitol at pH 7.5 overnight. GST-CrkII was then captured on glutathione–agarose beads and then incubated with lysates overexpressing flag-tagged paxillin for 1 h at 4 °C. Beads were then spun down and washed twice in HNTG buffer (0.1% Triton-X-100) and then boiled in SDS sample buffer.

High-throughput SH2 domain screens and bioinformatic analysis The Crk pY239 and pY251 phosphopeptides were spotted on a gelatincoated nitrocellulose membrane in register with the wells of a 96-well plate. Followed by incubation with soluble human GST-SH2 domains as probes (one in each well), HRP-conjugated GSH was used to detect and quantify binding by chemiluminescence as described before.⁴² The list of SH2 domain probes and clone information can also be found at (http:// www.addgene.org/Bruce_Mayer/). For bioinformatic analyses, predictions of SH2 interaction landscapes were made based on Artificial Neural Networks and Position-Specific Scoring Matrices through NetPhorest (http://netphorest.info/index.php).

Cell spreading and cell motility using xCelligence

For cell spreading, 10 000 viable cells were seeded into each well of fibronectin-coated E-plates (Acea BioSciences Inc.) after background measurement. Impedance to current through the electrodes is recorded every 30 s to generate cell index, a parameter directly proportional to the cell area in contact with the surface electrodes. For cell motility, 40 000 viable cells were seeded into each well of the upper chamber of (Cell Invasion and Migration (CIM)-plates, the undersides of which were coated with 10 μ g/ml Type I collagen. The lower chamber contained 10 or 25 ng/ ml EGF as the chemoattractant. Cell index was recorded every 15 min to generate real-time migration profiles.

Statistical analysis

Where indicated, statistical analysis was performed using SPSS (IBM Inc., Armonk, NY, USA) software. For Figure 5c and Supplementary Figure S3A, analysis of variance was performed without assuming equal variances across groups. Tamhane's T2 test was employed for *post hoc* analysis at a significance threshold of P=0.05. For Figure 5d top and middle panels, two-factor analysis at a significance threshold of P=0.05.

CONFLICT OF INTEREST

The authors declare no conflict of interest.

ACKNOWLEDGEMENTS

This work was supported by the NIH grant CA165077 to RBB and Rutgers Foundation grant to RBB and in part by NIH grant to CGK and RBB GM080308. The LC-MS/MS work was funded in part by an NIH grant NS046593, for the support of the Rutgers Neuroproteomics Core Facility. We thank Chingiz Underbayev, Wenl Tsou and Anita Antes for technical support; Sushil Kumar and Stanley Kimani for discussion.
